Computer Networks Assignment 1

This is my report for the first assignment of the Computer Networks course. The report is written in markdown and can be viewed in any markdown viewer. Each individual question has its own folder with a report and any images used in the report.

Problem 1

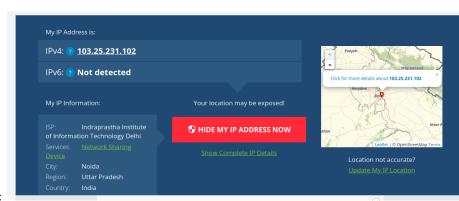

Part a

```
root@urmum-virtual-machine:/home/ur-mum/Documents/CN# ifconfig
ens33: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
        inet 192.168.232.129 netmask 255.255.255.0 broadcast 192.168.232.255
        inet6 fe80::1eaf:8055:f765:2a0b prefixlen 64 scopeid 0x20<link>
       ether 00:0c:29:cd:f6:82 txqueuelen 1000 (Ethernet)
RX packets 296954 bytes 327149471 (327.1 MB)
        RX errors 0 dropped 0 overruns 0 frame 0
        TX packets 108355 bytes 23366001 (23.3 MB)
        TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0
lo: flags=73<UP,LOOPBACK,RUNNING> mtu 65536
        inet 127.0.0.1 netmask 255.0.0.0
        inet6 ::1 prefixlen 128 scopeid 0x10<host>
        loop txqueuelen 1000 (Local Loopback)
        RX packets 97843 bytes 11792754 (11.7 MB)
        RX errors 0 dropped 0 overruns 0 frame 0
        TX packets 97843 bytes 11792754 (11.7 MB)
        TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0
```

Using ifconfig:

 $local/private\ ip\ address$

Part b

Using What is my ip address: global/public ip address

Both the IP addresses are different.

The difference between the two is that the local ip address is the ip address of the device on the local network, while the global ip address is the ip address of the device on the internet. The local ip address is assigned by the router, while the

global ip address is assigned by the ISP company that provides internet service to the user. This is done to reduce the number of IP addresses and abstract the IP addresses for security.

Problem 2

Part a

An authoritative answer is a response we get directly from the primary DNS server holding the master copy of the zone file.

To recieve an authorative answer we first must find the primary DNS server for the domain we are looking for. We can do this by using the nslookup command. For example, if we want to find the primary DNS server for google.com we can run the command nslookup -type=soa google.com which will return the primary DNS server for google.com which is nsl.google.com.

Now that we have the primary DNS server for google.com we can run the command nslookup google.com nsl.google.com which will return an authorative answer for google.com which is in the image below:

```
root@urmum-virtual-machine:/home/ur-mum/Documents/CN/CSE232-ComputerNetworks-Assignments/Assignment-1/Q2# nslookup -type=soa google.in
Server: 127,0.8.53
Address: 127,0.8.53453

Non-authoritative answer:
google.in
origin = nsl.google.com
mail addr = dns-admin.google.com
serial = 556730683
refresh = 900
retry = 900
expire = 1800
minimum = 60

Authoritative answers can be found from:
nsl.google.com internet address = 216.239.32.10
nsl.google.com has AAAA address 2001:4860:4802:32::a

root@urmum-virtual-machine:/home/ur-mum/Documents/CN/CSE232-ComputerNetworks-Assignments/Assignment-1/Q2# nslookup google.in nsl.google.com
Address: 216.239.32.10#53

Name: google.in
Address: 278.217.167.228
Name: google.in
Address: 2404:6800:4002:80f::2004
root@urmum-virtual-machine:/home/ur-mum/Documents/CN/CSE232-ComputerNetworks-Assignments/Assignment-1/Q2# 

Oddress: 2404:6800:4002:80f::2004
root@urmum-virtual-machine:/home/ur-mum/Documents/CN/CSE232-ComputerNetworks-Assignments/Assignment-1/Q2# 

Oddress: 2404:6800:4002:80f::2004
```

Figure 1: plot

for part (b):

Time to live of google.com DNS is 5 seconds. It will then be

Problem 3

Part a

The total hops are 10. One intermediatery router is _gateway(192.168.232.2). The average latency was is 0.506ms. The other is del11s22-in-f14.1e100.net(142.250.206.174).

Figure 2: plot

The average latency was 5.802ms. Rest of the routers are not shown in the output of the command traceroute www.google.com -I.

The output of the command traceroute www.google.com -I is shown below:

Figure 3: plot

The below result on windows is given by the command tracert www.google.com:

Part b

After pinging the URL "www.google.com" 50 times, I got an average of 9.009 ms. The exact output is shown below:

Part c

Adding up all intermediate router latencies, we get $0.506 \mathrm{ms} + 5.802 \mathrm{ms} = 6.308 \mathrm{ms}$. This is less than the average latency of pinging the URL "www.google.com" 50 times which is 9.009 ms. They are different as both traceroute and ping use different methods to calculate the latency. Traceroute uses ICMP packets to calculate the latency, while ping uses ICMP echo packets to calculate the latency.

```
:\WINDOWS\system32>tracert google.com
racing route to google.com [142.250.206.174]
over a maximum of 30 hops:
                14 ms
                           18 ms 192.168.32.254
       59 ms
                           2 ms vpn.iiitd.edu.in [192.168.1.99]
2 ms 103.25.231.1
       5 ms
                 2 ms
       4 ms
                 2 ms
                                  Request timed out. 10.119.234.162
                           6 ms
                 4 ms
                11 ms
                                  72.14.194.160
                                  74.125.243.97
                                  142.251.76.203
                  4 ms
                                  del11s22-in-f14.1e100.net [142.250.206.174]
                            3 ms
race complete.
```

Figure 4: plot

```
--- google.in ping statistics ---
50 packets transmitted, 50 received, 0% packet loss, time 49099ms
rtt min/avg/max/mdev = 5.516/9.009/64.666/8.123 ms
```

Figure 5: plot

Part d

Maximum of all intermediate router latencies is 5.802ms. This is less than the average latency of pinging the URL "www.google.com" 50 times which is 9.009 ms. This is because the latency of any one intermediate router will be less than all the intermediate routers.

Part e

The multiple entries in the traceroute output are due to the fact that the packets are being routed through different paths. This is because the routers are using different routing algorithms to route the packets. The routers are using different routing algorithms because they are different routers and they are using different routing algorithms to route the packets.

Part f

The average latency is 329.266 ms. The output of the command ping stanford.edu -c 50 is shown below:

Part g

The number of hops to stanford.edu is 27. This is much lower than google.com's 10 hops. The output of the command traceroute stanford.edu -I is shown below:

```
--- stanford.edu ping statistics ---
50 packets transmitted, 50 received, 0% packet loss, time 49084ms
rtt min/avg/max/mdev = 326.331/329.266/344.812/2.648 ms
```

Figure 6: plot

Figure 7: plot

Below is the output of the command tracert stanford.edu on windows:

Part h

The latency difference between stanford.edu and google.com is $329.266~\mathrm{ms}$ - $9.009~\mathrm{ms} = 320.257~\mathrm{ms}$. This is due to stanford.edu being farther away from my location than google.com. This is because the packets have to travel a longer distance to reach stanford.edu than google.com. This is also leads to the higher number of hops to stanford.edu than google.com.

Problem 4

To fail the localhost (127.0.0.1) with 100% packetloss, I made the firewal reject any input connection to the localhost. This can be done by running the command sudo iptables -A INPUT -p icmp --icmp-type echo-request -s 127.0.0.1 -j DROP. This will reject any input connection to the localhost. To test this I ran the command ping 127.0.0.1 which returned the below image:

To restore the localhost I ran the command sudo iptables -D INPUT -p icmp --icmp-type echo-request -s 127.0.0.1 -j DROP which will remove the rule that rejects any input connection to the localhost. To test this I ran

```
C:\WINDOMS\system32>tracert stanford.edu

Tracing route to stanford.edu [171.67.215.200]

over a maximum of 30 hops:
